Two Methods: [Deciding When to Prune Tomatoes](#) [Using Proper Pruning Techniques](#)

When growing tomatoes, the ultimate goal is to help the plant yield as much ripe fruit as possible. If you're growing indeterminate or "vining" varieties (Big Boy, Beef Master, most heirlooms), pruning your plants to remove unwanted shoots and leaves ensures that all the nutrients are going to the tomatoes. If you're growing a determinate variety (Biltmore, Heinz, Patio), too much pruning is counterproductive.

## Method 1

### Deciding When to Prune Tomatoes

**1 Determine which variety you're growing.** Before you make any cuts, figure out whether you're growing an indeterminate or determinate variety of tomato plant. Indeterminate varieties grow like vines, and they must be trained upright on poles and pruned in order to grow correctly. Determinate varieties contain themselves before they grow into a bush, and they naturally direct their energy toward fruiting without needing as much intervention. Here are the common varieties of each:

- **Indeterminate:** Big Boy, Beef Master, Black Prince, German Queen, most cherry tomato varieties and most heirloom varieties.
- **Determinate:** Ace 55, Amelia, Better Bush, Biltmore, Heatmaster, Heinz Classic, Mountain Pride and Patio.

**2 Check the plant for signs of yellowing.** One way to know when it is time to start pruning is to wait for the stems and leaves below the first set of flowers to turn yellow. When you notice this color change, you can start pruning.

**3 Check for suckers.** Look for the tiny new branches sprouting in the spot where a branch meets the stem on an indeterminate plant. These are called "suckers" and they're what you want to remove. Suckers left to grow will take energy from the rest of the plant and cause the plant to bear fewer fruits. This isn't always a bad thing, but strategically removing suckers will help your plant bear large fruit all season long.

**4 Look for flowers.** It is a good idea to start pruning your tomato plants early, as soon as there are flowers on the plants. At this point, the plants should be between 12 and 18 inches.<sup>[1]</sup>

## Method 2

### Using Proper Pruning Techniques

**1 Remove all suckers and their leaves below the first flower cluster.** Do this no matter what kind of tomato plant you have. This keeps the plant strong by helping it grow a sturdy central stem. <sup>[2]</sup> This should ensure that the majority of the nutrients are sent to the fruits, instead of being wasted on the unwanted growing tips.

- To remove a sucker, grab a growing tip by the base between the thumb and forefinger and bend it back and forth until it snaps cleanly. This should ideally be done when the shoot is young and supple. The small wound will heal quickly. This is called "simple pruning".
- As for stems and leaves, not the suckers, growing below the first flower cluster: If you live in a warmer zone such as Zone 9, you should leave them on until they turn yellow. They are important for helping to shade the ground until the plant matures. On the other hand, if your plant is in a humid environment (such as a greenhouse), remove *everything* below the first flower cluster to improve ventilation. Humidity can make it easier for sicknesses to flourish, and it also causes the wounds that are created while pruning to dry up more slowly making the plant longer vulnerable. By improving ventilation, you're helping to protect the plant.

**Leave the thicker shoots.** Thicker suckers should not be snapped off, since this could damage the whole plant. If it's thicker than a pencil, use the "Missouri pruning" method and pinch out just the tip of the sucker, leaving one or two leaves behind for photosynthesis and to protect developing fruit from sun scald. The drawback is that suckers will develop from the stem that you leave behind, which will require additional pruning. This technique is better when you're dealing with large suckers; if the wound becomes diseased, it will be further away from the main stem. This method also leaves a few inches on the sucker to reduce the shock to the plant.

- Prune suckers all summer long to keep the plant healthy. They grow quickly, so you may need to prune once or twice a week.<sup>[3]</sup>

**3 Pinch off all but four or five fruit bearing trusses for indeterminate varieties.** These are the branches that grow from the main stem above the first flower cluster. Four or five will produce large, healthy fruit, but any more than that and the fruit will be small and scant. Choose four or five sturdy trusses to keep, then pinch out any additional side shoots, leaving the plant's top shoot intact, known as the terminal shoot.

- Make sure the vine-like plants are tied to supports after flowering occurs. Otherwise, the vine will grow along the ground and won't produce healthy tomatoes.<sup>[4]</sup>
- Determinate plants already have a predetermined number of stems that will naturally grow, so there's no need to do any pruning above the flower cluster. If you prune above the flower cluster, you'll be removing fruit-bearing branches without helping the plant.<sup>[5]</sup>

**4 Remove yellow leaves.** Yellow leaves are leaves that use up more sugar than they produce. As the plant begins to mature, the lower leaves will naturally begin to yellow and wilt. This is perfectly normal, so pull these from the plant when they appear. It will keep the plant fresh and help ward off disease.

**5 Top the plant.** To get the best out of the last growth of the season, it is necessary to "top" the plant. About a month before the first expected frost, or when the plant hits the roof of your greenhouse, remove the plant's terminal shoot. At this point in the season, the tomatoes currently growing will have a limited time to reach maturity, so all nutrients must be directed straight to the fruit.

## Community Q&A

### When should I start pruning?

 You can start pruning safely after the first set of flowers appears. Some growers like to prune the bottom set of limbs when transplanting tomatoes out to the field.

### Should my tomato plants be trimmed if they are brown and have dead leaves?

 Yes, you should trim off any dead, diseased or broken limbs.

### I have beef steak and better boy plants. They are up to about 5 feet tall and have very few tomatoes on them. What should I do?

 You can self-pollinate the tomato flowers with an electric toothbrush. Turn the brush on and hold it to the back of the flower -- it releases pollen. Every bloom I've done this to has turned into a tomato.

### What is the determining factor that make my tomatoes determinate or indeterminate plants?

 The vast majority of tomatoes for sale are indeterminate. Look for words like "patio" or "bush" that would suggest a compact, or determinate plant.

### How long do tomato plants live, and do they die off every year?

 They live until the first frost, or until they get blight from rainy/moist weather. Unless you live in a tropical area or have a greenhouse, they will die every year.

**How tall should I allow a tomato plant to grow?**wikiHow  
Contributor

Until you see tomatoes form on most of the branches. Then cut off the branches that still have only flowers (or no flowers) and the flowers that have not produced fruit.

**Should I remove the leaf stem below a sucker rather than the sucker itself? I have heard that it is a better way to do it.**wikiHow  
Contributor

No. The sucker will try to produce more fruit. The fruit should be made on the main stem.

**Can I pinch off early blossoms?**

Sander1

You can, but why would you? Those blossoms will bear tomatoes, so I'd just let them grow.

**Do my tomato plants need calcium if the bottoms of the tomatoes are brown?**wikiHow  
Contributor

Yes, either a calcium spray, which you can make from water and one of the calcium products intended to stop fruit rot, or a fertilizer with calcium in it applied just above the roots will solve the problem.

**Tips**

- Determinate or "bush" varieties do not need pruning (or staking, for that matter). They are bred to grow to a compact height, produce one "wave" of fruit during a two weeks period and then die. Indeterminate varieties, also called "vining" tomatoes, grow as tall as people and produce and grow all season long. Common determinate varieties are Rutgers, Roma, Celebrity (called a semi-determinate by some) and Marglobe. Common indeterminate varieties are Big Boy, Beef Master, most "cherry" types, Early Girl and most heirloom varieties. <sup>[6]</sup>

## Warnings

- To avoid infecting your **tomato plants**, always prefer fingers over blades for removing shoots (the resulting wound can be easily infected). However, for older, tougher shoots, you may have to resort to using a blade; if so, sterilize your cutting implement thoroughly for each use.
- If you smoke, wash your hands thoroughly with soap and water before handling tomato plants. Tobacco smokers can easily infect tomato plants with "Mosaic Virus."

## Things You'll Need

- ☐ Growing tomatoes
- ☐ Clean hands
- ☐ Sterilised cutting implement *if* using (hands preferred)
